Summary

`JustRelax.jl` is an open source, highly portable, and high-performance Julia (Bezanson et al., 2017) package designed for geodynamic modeling. It employs the Accelerated Pseudo-Transient (APT) method to solve the Stokes and diffusion equations, making it well-suited to exploit Graphics Processing Unit (GPU) hardware accelerators.

`JustRelax.jl` incorporates a wide range of features critical to computational geodynamics, including complex and highly non-linear rheologies, free surface, and a particle-in-cell method to advect material information. Several of the features available in `JustRelax.jl` are are outsourced to specialized external packages, reducing the core code base, and improving maintainability and reusability.

Statement of Need

Simulating Earth's thermo-mechanical evolution requires solving coupled, nonlinear Stokes and heat-diffusion problems across large domains with sharp material contrasts, complex rheologies and long time scales. These calculations are computationally demanding and traditionally rely on monolithic, CPU-oriented codes built around matrix-based linear solvers. Such designs are hard to port efficiently to modern heterogeneous HPC systems (e.g. multi-GPU nodes).

`JustRelax.jl` addresses this gap by providing a compact, modular, GPU-ready toolkit implemented in Julia. It implements a matrix-free Accelerated Pseudo-Transient (APT) solver that reduces global linear-algebra bottlenecks and ports efficiently to accelerators, while outsourcing some physical calculations, parallalelization, and IO to other packages, shown in 1. This keeps the core solver as contained as possible and makes the software more flexible. Julia's high-level syntax and package manager simplify installation, scripting and extension, lowering the barrier for students and researchers to prototype and test new physics.

The Journal of Open Source Software

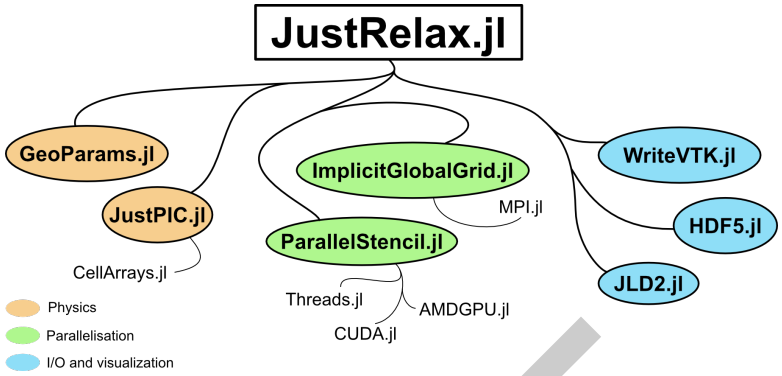

Figure 1: Sketch of the main dependencies of `JustRelax.jl`: a) physics packages: material properties and rheology (GeoParams.jl (Kaus et al., 2025)), Particles-in-Cell based advection (JustPIC.jl (Montserrat et al., 2025), where data structures are handled by CellArrays.jl); b) parallelization: domain decomposition and distributed parallelism is handled by ImplicitGlobalGrid.jl (Omlin et al., 2024) and MPI.jl [Byrne2021], and backend abstraction is implemented with ParallelStencil.jl (Omlin et al., 2024), which supports Julia's native multi-threading (Threads.jl), and NVIDIA (CUDA.jl [besard2018juliagpu]) and AMDGPU.jl GPU cards; and c) I/O and data visualization: HDF5 binary files (HDF5.jl and JLD2.jl), and VTK files for visualization (WriteVTK.jl (Polanco, 2023)).

In short, `JustRelax.jl` delivers a high-performance, portable alternative to legacy geodynamics codes: it (i) exploits modern GPUs without extensive rewrites; (ii) avoids costly matrix assembly via matrix-free algorithms; and (iii) promotes modularity, reproducibility, and rapid development. Together with CI, scalable I/O and checkpointing, these features make `JustRelax.jl` practical for both exploratory studies and production-scale simulations on modern multi-XPU platforms.

Methods

`JustRelax.jl` solves the (in)compressible Stokes equations, described by the equations of conservation of momentum and mass, as well as the conservation of energy equation. This system of equations is solved using the APT method (Räss et al., 2022), which transforms the PDEs into damped wave equations by augmenting them with a second order pseudo-time derivative which should vanish upon convergence, thus recovering the original form of the PDE. For an in-depth description of this method, we refer the reader to Räss et al. (2022).

Package summary

`JustRelax.jl` features:

- **High-performance and scalable matrix-free solver**: `JustRelax.jl` implements the APT method for (in)compressible Stokes and diffusion problems to circumvent the need for computationally expensive linear algebra operations and direct solvers, significantly improving computational efficiency for large-scale simulations. The embarrassingly parallel nature of the APT method makes it an excellent solver to exploit hardware accelerators. The weak scaling curve of the 3D Stokes solver is shown in Fig. 2, where the parallel efficiency is the wall-time of any simulation normalized by the wall-time of a single process simulation ($t_{\text{parallel}}/t_{\text{series}}$). Distributed parallelism across multiple CPU/GPU nodes is achieved with ImplicitGlobalGrid.jl (Omlin et al., 2024).

the wall-time of the single-process run normalized by the product of the number of processes and the wall-time of the parallel run

- **Advanced non-linear rheology**: The package supports a comprehensive suite of geologically relevant rheology models, such as visco-elasto-plastic and non-Newtonian constitutive laws, allowing for simulations with complex Earth-like materials, essential for modeling geological processes at a wide range of scales. All the local material physics calculations are computed by GeoParams.jl (Kaus et al., 2025).
- **Portability**: `JustRelax.jl` is designed to run efficiently on multiple hardware architectures, including CPUs, GPUs (CUDA and AMD), and on multi-node clusters. This portability is achieved through Julia's advanced meta-programming capabilities, which generate the code for the specific target hardware during compile or parse time. This abstraction of the hardware backend is implemented in ParallelStencil.jl (Omlin et al., 2024).
- **Continuous integration (CI) and testing**: The package is tested and validated against a suite of benchmarks and model examples to ensure correctness and performance on various hardware. The default CI/CD pipeline is implemented using GitHub Actions, automatically running tests on every commit and pull request. Single GPU CI is run on using JuliaGPU Buildkite and multi-GPU CI executes on the Swiss National Supercomputing Centre (CSCS) ALPS supercomputer. This ensures that the package remains robust and reliable across different hardware architectures and Julia versions.

Examples

An extensive set of benchmarks and model examples are available in the GitHub repository of `JustRelax.jl`. Some examples such as shear band localization, 2D subduction or the rise of a 3D plume are described in the documentation. Here we limit ourselves to show some snapshots of the results of these examples in Fig. 3.

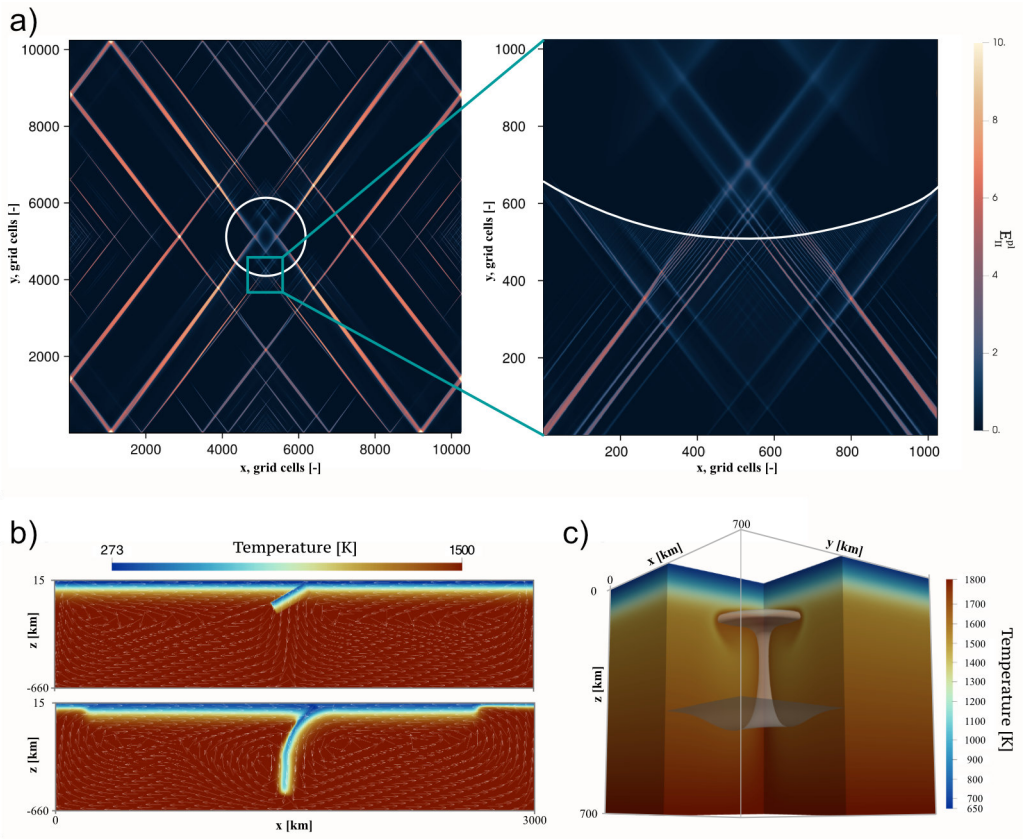

Figure 3: Model examples from the documentation: a) Second invariant of the plastic strain tensor ($E_{II}^{pl}) heatmap of 2D shear band localization of a visco-elasto-viscoplastic body (10240×10240 cells), b) 2D subduction (512×512 cells), and c) raising of a hot plume in 3D ($128 \times 128 \times 128$ cells). All models were run on one NVIDIA GH200 Grace Hopper GPU.
