## 5 Summary

6 Power analysis is a critical step in the design of psychological and behavioral experiments, yet  
7 existing tools often lack the flexibility to accommodate complex ANOVA designs. pwranova is  
8 an R package that performs power analysis for between-, within-, and mixed-factor ANOVA  
9 designs, with full support for main effects, interactions, and planned contrasts (custom contrasts  
10 with user-defined weights).

11 The package allows researchers to calculate statistical power, required total sample size,  
12 significance level, or minimal detectable effect sizes expressed as partial eta squared or Cohen's  
13  $f$ .

14 In addition to ANOVA, pwranova provides complementary functions for common related tests,  
15 including  $t$ -tests (one-sample, paired, and two-sample) and tests of Pearson's correlation  
16 (using either the  $t$ -distribution or Fisher's  $z$ -transformation approach). This makes the package  
17 a convenient toolkit for planning experimental studies in psychology and related fields.

## 18 Statement of need

19 Researchers in psychology and the behavioral sciences frequently rely on analysis of variance  
20 (ANOVA) to analyze factorial designs with multiple between- and within-participant factors.  
21 However, existing tools such as GPower ([Faul et al., 2007](#)) and the pwr R package ([Champely,  
22 2020](#)) offer only limited flexibility when it comes to handling such complex designs. For example,  
23 specifying interactions in multi-factor mixed designs is difficult or not directly supported in  
24 these tools. They also generally do not allow direct specification of user-defined contrasts, and  
25 while effect sizes can be specified via Cohen's  $f^*$  ([Cohen, 1988](#)), they do not directly support  
26 partial eta squared, which is more commonly reported in psychological research as a standard  
27 effect size index.

28 pwranova addresses these limitations by providing:

- 29 - Support for between-, within-, and mixed-factor ANOVA designs, including both main effects  
30 and interactions.
- 31 - Power analysis for planned contrasts with flexible, user-defined weight specification.
- 32 - Methods based on the noncentral  $F$ -distribution.
- 33 - Integrated functions for related  $t$ -tests and Pearson correlations.
- 34 - A unified and extensible R implementation designed for reproducible research workflows.

35 In addition, pwranova not only extends power analysis to complex factorial ANOVA designs  
36 but also incorporates related  $t$ -tests and correlation tests within the same framework. This  
37 integration allows researchers to conduct power analysis for a wide range of commonly used  
38 statistical tests in a consistent and reproducible way.

39 This combination of flexibility and reproducibility makes pwranova especially useful for experi-  
40 mental psychologists and cognitive scientists, as well as researchers in the behavioral, social,

41 and biological sciences designing studies with complex factorial structures. Detailed examples  
42 and tutorials are available on the package website:  
43 <https://mutopsy.github.io/pwrANOVA/>
