Summary

GIBBON (K. M. Moerman 2017), which loosely stands for Geometry and Image-Based Bioengineering add-ON, is an open-source MATLAB® toolbox providing a single open-source framework for many aspects of computational (bio)mechanics such as: image segmentation, meshing, boundary conditions specification, finite element analysis (FEA), and visualization. A schematic of the core functionality of GIBBON is shown in the figure below.

Below is a more detailed discussion of the core functionality where reference is made to implementations in the documentation.

- **Image segmentation:** In patient-, or subject-specific biomechanics, the geometry information is often derived from image data (e.g. Magnetic Resonance Imaging (MRI)). GIBBON offers image filtering and smoothening methods, and has a graphical user interface for 3D image segmentation (see `HELP_imx.m`). The segmented image data can be converted to 3D surface models which can be meshed for FEA.
- **Computer Aided Design (CAD) tools:** Sometimes geometry is instead imported or designed. Using GIBBON geometry can be imported from common mesh based CAD files (such as STL, see `HELP_import_STL`). However, several CAD style commands have also been implemented in GIBBON such as polygon rounding, revolution (see `HELP_polyRevolve`), extrusion (see `HELP_polyExtrude`), and sweeping and lofting (see `HELP_polyLoftLinear` and `HELP_sweepLoft`).
- **Surface meshing tools:** 2D multi-region triangular meshing (see for instance `HELP_regionTriMesh2D` and `HELP_multiRegionTriMeshUneven2D`), resampling meshes geodesically (see `DEMO_geodesic_remeshing`), smoothening (`DEMO_surface_smooth_methods`), and surface mesh refinement (see `HELP_subtri`, `HELP_subTriDual` and `HELP_subQuad`), mesh type conversions (see `HELP_tri2quad`, `HELP_quad2tri`), and mesh dual computation (see `HELP_patch_dual`). Geometries can also be exported to the STL format e.g. for computer aided manufacture and 3D printing.
- **Volumetric meshing:** Tetrahedral meshing (and constrained Delaunay tessellation) of multi-region domains is enabled through an interface with the [TetGen](#) (Si 2015) package (`HELP_runTetGen`). Hexahedral meshes for some geometry types can be directly coded (e.g. sphere `HELP_hexMeshSphere`, boxes `HELP_hexMeshBox` and lattices `HELP_element2HexLattice`). For general input surfaces multi-region mixed tetrahedral-hexahedral meshing is also available (`DEMO_MixedTetHexMeshing`).
- **Lattice structures:** Various lattice structure tools have been implemented. One method to generate surface geometry for lattices is the use of triply-periodic functions (see `HELP_triplyPeriodicMinimal` and `DEMO_FEBio_trabeculae_compression`).

Figure 1: A Graphical summary of the GIBBON toolbox

Functions to convert element descriptions, such as tetrahedral and hexahedral elements, to lattice structures have also been implemented (`HELP_element2lattice` and `HELP_element2HexLattice`). These allow for the creation of 3D boundary conforming lattice structures on arbitrary input geometry. Exporting of hexahedral elements is also supported allowing for FEA on the created lattice structures.

- **Finite element analysis (FEA):** GIBBON interfaces with the free software [FEBio](#) (Maas et al. 2012) for FEA (source code available on FEBio website). GIBBON can be used as a pre- and post- processor for FEA as it enables the code based development of meshes, boundary conditions, and input files. FEBio files can be directly exported based on dedicated MATLAB® structures. Furthermore, GIBBON can be used to start and control FEBio simulations. As such, iterative and inverse FEA (e.g. based on MATLAB® optimization routines) is also enabled. All `DEMO_FEBio_...` files contain FEBio examples, `DEMO_FEBio_iFEA_uniaxial_01` is a simple inverse FEA example.

- **Visualization**

GIBBON expands the standard MATLAB® visualization capabilities by adding 3D image and voxel visualization (see `HELP_im2patch` and `HELP_sliceViewer`), meshed geometries (`HELP_gpatch`), finite element models (`HELP_element2patch`), and colormapped vector data (`HELP_quiverVec`), and all visualization methods enable multiple colormaps to be used in each figure or axis window. Furthermore GIBBON offers a custom figure window `cFigure` containing 3D rotation options (`HELP_vcw`) that mimic CAD behavior of 3D scene rendering, and high quality figure exporting options (`HELP_efw`). Advanced graphics animation creation and exporting capabilities through a figure window based GUI are also enabled (see `HELP_anim8`).

To date GIBBON has been used for image analysis and visualization (K. Moerman et al. 2012), continuum mechanics (K. M. Moerman 2017), soft tissue biomechanics ((Cooney et al. 2015) (M. Takaza, Moerman, and Simms 2013)), and subject-specific and inverse FEA of soft biological soft tissue *in-vivo* ((K. M. Moerman 2017) (D. Sengh et al. 2016)). Current research with GIBBON is focused on subject-specific computational modeling for

the automated generation of 3D printable prosthetic devices with optimized and spatially varying mechanical behavior (K. M. Moerman, Sengeh, and Herr 2016).

Acknowledgements

GIBBON has not received dedicated funding but development of GIBBON has taken place as part of several other research projects. As such GIBBON has been partially financially supported by: Science Foundation Ireland (Research Frontiers Grant No. 06/RF/ENMO76) in the period 2006-2010, the Dutch Technology Foundation (project 12398) in the period 2012-2015, the Robert Wood Johnson Foundation (RWJF-ID72293) in the period 2015-2016, National Institute of Health (R01EB024531-01) presently.
