## <sup>12</sup> Summary

<sup>8</sup> QuaRT is a Python library for quantum simulation of radiative transfer in astrophysical and  
<sup>9</sup> cosmological problems.

<sup>10</sup> The source code for QuaRT is available on [GitHub](#). It can be installed via pip from the [pypi](#)  
<sup>11</sup> index. Its [documentation](#) is hosted publicly.

## <sup>12</sup> Statement of need

### License

Computational cosmology, the use of simulations to study the evolution of the universe, is a rapidly-growing field of research, driven largely by the exponential increase in computing power following Moore's law. Numerous codes (Brummel-Smith et al., 2019; Bryan et al., 2014; Davis et al., 2012; Hayes & Norman, 2003; Ilian T. Iliev et al., 2006; Ilian T. Iliev et al., 2009; Jiang et al., 2014; Rahul Kannan et al., 2019; R. Kannan et al., 2021; O'Shea et al., 2015) have been written to study questions about the early universe and to obtain a better understanding of the plethora of observational results which have come with new telescopes such as the James Webb Space Telescope (Adams et al., 2024). However, classical high-performance computing hardware is slowly approaching the fundamental quantum limit where electronics cannot be scaled down any further (Powell, 2008). Quantum computers present a potential path for further scaling of physical simulations by taking advantage of quantum phenomena such as superposition and entanglement which enable new models of computation. Many quantum algorithms have already been developed for the simulation of cosmological problems (Joseph et al., 2021, 2022; Kaufman et al., 2019; Liu & Li, 2021; Mocz & Szasz, 2021; Wang & Wu, 2024; Yamazaki et al., 2025). Such simulations must model physical processes such as radiation transport from stars, magnetohydrodynamics of matter, gravitation between massive particles, gas chemistry, and the formation of structures such as stars, black holes, halos, and galaxies (e.g., Brummel-Smith et al., 2019; Hopkins et al., 2023). Of these, radiation transport tends to be one of the most expensive steps due to the high dimensionality of the problem, but it also the most difficult to develop because of the lack of problems with analytical solutions (Ilian T. Iliev et al., 2006; Ilian T. Iliev et al., 2009). Quantum algorithms have been formulated for radiation transport, such as those based on ray tracing (Lu & Lin, 2022a, 2022b, 2023; Mosier, 2023; Santos et al., 2025), random walks (Lee et al., 2025), and other novel differential equations solvers (Gaitan et al., 2024). Classical lattice Boltzmann methods (LBMs), which track the distribution of a quantity on a grid with discretized propagation directions (McNamara & Zanetti, 1988), have already been applied extensively to study radiation transport (Bindra & Patil, 2012; McCulloch & Bindra, 2016; Mink et al., 2020; Olsen & Rezzolla, 2025; Weih et al., 2020) and radiation hydrodynamics (Asahina et al., 2020). Quantum LBMs have also been constructed to study hydrodynamics (Budinski, 2021; Ljubomir, 2022; Wawrzyniak, Winter, Schmidt, Indiniger,

et al., 2025; Wawrzyniak, Winter, Schmidt, Indinger, et al., 2025) and radiation transport (Igarashi et al., 2024). These quantum LBMs reduce the memory constraints of classical simulations by storing information in quantum state amplitudes, the number of which grows exponentially with the number of qubits, enabling the storage of data with only logarithmic scaling with problem size. Individual simulation steps can thus be made very high resolution and only the necessary amount of data needs to be stored classically. However, existing quantum LBMs are not suited for cosmological problems because such simulations are typically non-scattering, but isotropic sources under stars are not accurately resolved angularly by LBMs due to their discretized angular structure. QuaRT features the first known implementation of a quantum LBM which accurately resolves isotropic sources in non-scattering media; it does so via a novel methodology which we refer to as “angular redistribution”, where radiation is redistributed between angular directions based on the expected angular distribution. This can even be done globally for an entire simulation domain with no increase in computational complexity, enabling larger and more accurate simulations of the evolution of the universe than currently possible.

## 58      **Functionality**

59      QuaRT uses Qiskit for circuit construction and Qiskit Aer for circuit execution (Javadi-Abhari  
60      et al., 2024).

61      The qlbm\_rt module features the simulate method which is called to perform simulations  
62      with the lattice Boltzmann method. This method constructs the full quantum circuit for each  
63      timestep of the simulation and returns the lattice data.

64      The qlbm\_circuits module features constructors for the necessary circuits for radiative transfer  
65      simulation in 1D, 2D, and 3D, including a constructor for the novel angular redistribution step.  
66      These constructors are called by the simulate method which composes them to construct the  
67      full quantum circuit.

68      QuaRT features a variety of utility methods for both general and quantum lattice Boltzmann  
69      methods in lbm\_utils and qlbm\_utils, respectively. It also features analysis utilities in the  
70      analysis module. These utilities are used by the simulate method for problem setup and  
71      analysis.

72      The test module features a variety of common test cases used for radiative transfer codes,  
73      including the isotropic source, opaque cloud shadow, and crossing radiation beams tests. These  
74      tests demonstrate the general correctness of the codebase, with a particular emphasis on the  
75      performance of the angular redistribution methodology.

76      There is also a set of demo notebooks including a fully-classical implementation for comparison  
77      with the quantum algorithm and some unit tests of experimental features.

## 78      **Scholarly Work**

79      QuaRT is currently being used to study lattice Boltzmann methods for radiative transfer (Devkota  
80      & Wise, 2025, in prep.).

## 81      **Acknowledgements**

82      JHW acknowledges support from NSF grants AST-2108020 and AST-2510197 and NASA grant  
83      80NSSC21K1053. This research was supported in part through research cyberinfrastructure  
84      resources and services provided by the Partnership for an Advanced Computing Environment  
85      (PACE) at the Georgia Institute of Technology, Atlanta, Georgia, USA (PACE, 2017).
