⁸ Summary

⁹ The description of the plasma state for non-axisymmetric magnetic confinement fusion devices
¹⁰ (stellarators) is a non-trivial task. It can be modelled by a three-dimensional equilibrium
¹¹ solution of the ideal magnetohydrodynamic (MHD) equations, in which pressure and magnetic
¹² field forces are balanced.

¹³ The Galerkin Variational Equilibrium Code (GVEC) is a new code for finding 3D MHD
¹⁴ equilibrium solutions, given a plasma boundary shape.

¹⁵ A distinct feature of GVEC is a flexible coordinate frame, which can represent complex plasma
¹⁶ boundary shapes with simple cross-sections ([Hindenlang et al., 2025](#)). This allows exploration
¹⁷ of a wider variety of plasma states, which might not be representable in the usual cylindrical
¹⁸ coordinates.

Statement of need

MHD equilibrium solutions are the basis for a number of high fidelity plasma physics models and associated codes. For example, they provide the initial conditions for linear and nonlinear MHD solvers (e.g. CASTOR3D ([Puchmayr et al., 2023](#)), CAS3D ([Schwab, 1993](#)), Jorek3D ([Nikulsin et al., 2022](#)), Struphy ([Holderied et al., 2021](#)), M3D-C1 ([Jardin, 2004](#))), or the magnetic field for particle orbit tracing (e.g. SIMPLE ([Albert et al., 2020](#))) and turbulence simulations (e.g. BOUT++ ([Shanahan et al., 2024](#)), GENE ([Bañón Navarro et al., 2020](#))).

3D MHD equilibria are directly used to analyse potential stellarator configurations in optimisation frameworks, such as SIMSOPT ([Landreman et al., 2021](#)) or STELLOPT ([Lazerson et al., 2020](#)).

GVEC has a flexible coordinate frame, allowing it to represent boundary shapes beyond those possible with the standard cylindrical coordinates used by many equilibrium codes. This has been recently used to optimise the boundary shape of the figure-8 stellarator in [Plunk et al. \(2025\)](#), shown in [Figure 1](#).

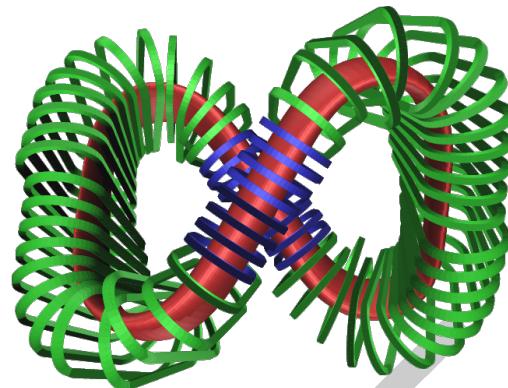

Figure 1: Preliminary design of a Figure-8 shaped stellarator, showing the plasma boundary shape and a set of planar coils to contain the plasma. Figure taken from Plunk et al. (2025)

33 Features

34 The approach used in GVEC to find solutions to the 3D MHD equilibrium problem is the same
 35 as used in VMEC, proposed by Hirshman & Whitson (1983). In this approach, the total MHD
 36 energy is minimised using a gradient descent method, under the assumption of nested flux
 37 surfaces. This assumption allows the use of flux-aligned coordinates, which consist of a radial
 38 coordinate ρ labelling the flux surfaces, and two periodic coordinates ϑ and ζ , parametrising
 39 each surface. An example is shown in Figure 2. The MHD equilibrium is then found by moving
 40 the flux surface geometry, while the boundary shape and radial profiles (related to plasma
 41 pressure and magnetic field representation, such as the rotational transform) are kept fixed.

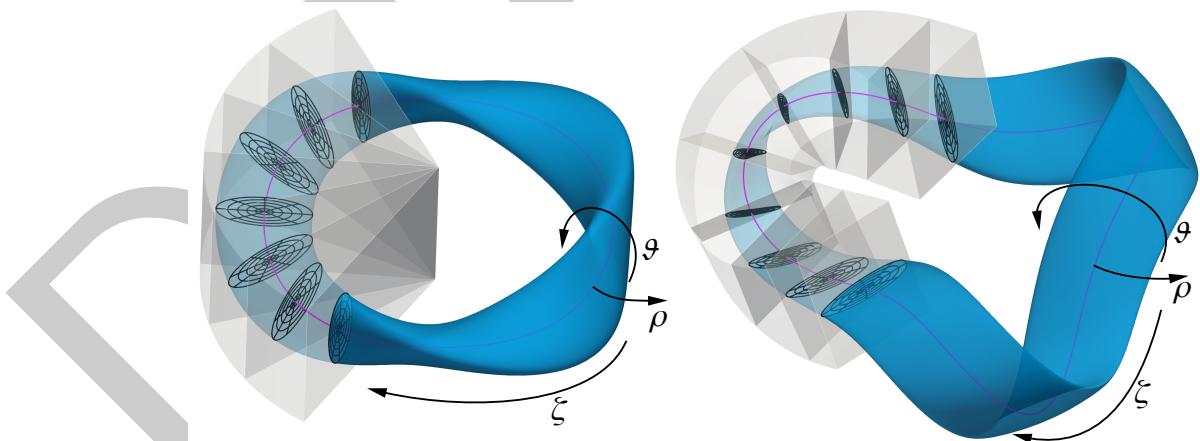

Figure 2: Two examples of stellarator equilibria computed in GVEC, either represented in cylindrical coordinates (left) or in a flexible coordinate frame, following a strongly shaped boundary (right). The flux-aligned coordinates are indicated, with a radial coordinate ρ and two angular coordinates ϑ and ζ . In each planar cross-section $\zeta = \text{const}$, a (ρ, ϑ) grid (black) is shown, as well as the boundary surface (blue) at $\rho = 1$ and the magnetic axis (purple) at $\rho = 0$.

42 In GVEC, the flux surface geometry can be represented in the usual cylindrical coordinates,
 43 but also in a flexible coordinate frame, enabling cross-sections to be aligned with the boundary
 44 shape, as shown in Figure 2. Details are found in Hindenlang et al. (2025).

45 Furthermore, the unknowns of the solution in GVEC are represented using a tensor-product
 46 of B-splines in the radial direction and Fourier series in the two angular directions. A linear

47 constraint ensures that the solution remains smooth across the polar singularity at $\rho = 0$. It is
48 also possible to impose axisymmetry (tokamaks), stellarator-symmetry and discrete rotational
49 symmetry (number of field periods). Both configurations shown in Figure 2 have three field
50 periods and are stellarator-symmetric.

51 GVEC is provided as a python package with core routines written in modern Fortran and
52 parallelised with OpenMP and MPI. The python package allows for simplified installation,
53 execution and post-processing. It can be controlled via the command line or using a python
54 API.

55 Additional features are:

- 56 ■ possibility to initialise from existing GVEC solutions;
- 57 ■ execution of consecutive runs via “stages”, allowing parameter changes, e.g. for refine-
58 ment, boundary perturbations or optimisation;
- 59 ■ automatic optimisation of the rotational transform profile for targeting a desired toroidal
60 current profile;
- 61 ■ possibility to initialise a stellarator configuration from the QUASR database (Giuliani,
62 2024), with an automatically constructed coordinate frame;
- 63 ■ post-processing interfaces to CAS3D, CASTOR3D, GENE, Jorek3D, SIMPLE and Stru-
64 phy.

65 Related software

66 Various other ideal MHD equilibrium solvers for 3D geometries exist. In the past, VMEC
67 (Hirshman & Whitson, 1983) has been most commonly used. It uses finite differences radially
68 and Fourier series for the flux surfaces. VMEC has recently been re-implemented in a more
69 modern framework as VMEC++ (Schilling, 2025). The stellarator optimisation framework
70 DESC (Dudt & Kolemen, 2020) is also capable of finding ideal MHD equilibria under the
71 assumption of nested closed flux surfaces, using smooth Zernike-Fourier basis functions for the
72 unknowns.

73 Other MHD equilibrium solvers exist that do not rely on flux-aligned coordinates, and therefore
74 allow the computation of 3D MHD equilibria with magnetic islands and chaotic regions. SPEC
75 (Hudson et al., 2020) uses the multi-region relaxed MHD model (Hole et al., 2006) and HINT2
76 (Suzuki et al., 2006) uses a relaxation method. Similarly, the codes SIESTA (Hirshman et al.,
77 2011) and PIES (Reiman & Greenside, 1986) use iterative techniques to find such 3D MHD
78 equilibria, starting from a VMEC equilibrium solution.

79 Acknowledgements

80 The authors would like to thank the MPCDF team for their services and constant support. We
81 thank the stellarator theory group at IPP in Greifswald for their advice and close collaboration,
82 in particular G. Plunk, C. Nührenberg, A. Goodman, J. Geiger and M. Borchardt. We also
83 like to thank A. Banon Navarro, D. Jarema, M. Maurer, R. Ramasamy, E. Strumberger and J.
84 Puchmayr for their contributions, in particular to the interfaces with other codes.

85 The authors are also grateful to the contributors to the open source software projects f90wrap
86 (Kermode, 2020), Xarray (Hoyer & Joseph, 2017) and SeLaLib (Navaro et al., 2021), without
87 which this project would not have been possible in this way.

88 Parts of this work has been carried out within the framework of the EUROfusion Consortium,
89 funded by the European Union via the Euratom Research and Training Programme (Grant
90 Agreement No 101052200 — EUROfusion). Views and opinions expressed are however those
91 of the author(s) only and do not necessarily reflect those of the European Union or the

⁹² European Commission. Neither the European Union nor the European Commission can be
⁹³ held responsible for them.
