## <sup>5</sup> Summary

<sup>6</sup> Flexible Round-Optimized Schnorr Threshold Signatures (FROST), standardized in IETF RFC  
<sup>7</sup> 9591 ([Connolly et al., 2024](#)), enable a set of participants to collaboratively produce Schnorr  
<sup>8</sup> signatures while distributing signing authority across multiple parties. The FROST protocol  
<sup>9</sup> was originally introduced by Komlo and Goldberg ([Komlo & Goldberg, 2021](#)). As threshold  
<sup>10</sup> signatures gain adoption in distributed infrastructures and blockchain systems, there is a  
<sup>11</sup> growing demand for implementations that integrate with existing high-assurance cryptographic  
<sup>12</sup> libraries.

<sup>13</sup> **secp256k1-frost** is an open-source implementation of FROST written in portable C (C89)  
<sup>14</sup> and designed as an extension module for the widely used `libsecp256k1` library ([Wuille](#)  
<sup>15</sup> & [contributors, 2021](#)). The project implements the protocol logic defined in RFC-9591  
<sup>16</sup> while reusing the elliptic-curve arithmetic and engineering practices of `libsecp256k1`. The  
<sup>17</sup> implementation emphasizes minimal dependencies, auditability, and interoperability with  
<sup>18</sup> `secp256k1`-based software, making it suitable for experimentation, research, and integration  
<sup>19</sup> into performance-critical systems.

## <sup>20</sup> Statement of Need

<sup>21</sup> Threshold signatures are increasingly used in distributed systems, digital asset infrastructures,  
<sup>22</sup> and secure multiparty applications. Despite the standardization of FROST, developers  
<sup>23</sup> integrating threshold signing into existing `secp256k1`-based environments face practical  
<sup>24</sup> challenges, including dependency-heavy implementations and limited availability of low-level C  
<sup>25</sup> libraries aligned with established cryptographic toolchains.

<sup>26</sup> Existing FROST implementations are often written in higher-level languages or rely on  
<sup>27</sup> broader cryptographic frameworks. In contrast, `secp256k1-frost` focuses on a minimal C  
<sup>28</sup> implementation aligned with the engineering philosophy of `libsecp256k1`, enabling standards-  
<sup>29</sup> compliant threshold signing without introducing additional cryptographic dependencies.

<sup>30</sup> The library addresses the needs of developers and researchers requiring:

- <sup>31</sup> ▪ portable and minimal-footprint cryptographic components,
- <sup>32</sup> ▪ compatibility with `secp256k1`-based infrastructures,
- <sup>33</sup> ▪ deterministic builds and auditability,
- <sup>34</sup> ▪ experimentation with RFC-9591-compliant threshold signing workflows.

## <sup>35</sup> State of the Field

<sup>36</sup> Several open-source implementations of FROST have emerged alongside the standardization  
<sup>37</sup> process, spanning multiple programming languages and elliptic-curve ciphersuites. The CFRG

38 draft repository maintains a list of existing implementations, including [reference prototypes](#)  
39 in Sage, Rust-based libraries supporting multiple curves (e.g., ristretto255, ed25519, and  
40 secp256k1), and implementations in languages such as Go ([Connolly et al., 2024](#)). Many of  
41 these projects emphasize modularity and generic protocol abstractions, enabling experimentation  
42 across different curves and deployment environments.

43 Notably, Rust implementations such as the Zcash Foundation FROST library provide flexible  
44 multi-ciphersuite support and have contributed significantly to the maturation of the ecosystem  
45 ([Zcash Foundation, 2023](#)). However, these implementations typically rely on higher-level  
46 cryptographic frameworks and introduce additional dependency layers that may complicate  
47 integration into minimal or embedded environments.

48 In contrast, secp256k1-frost explores a complementary design space by extending the existing  
49 libsecp256k1 ecosystem ([Wuille & contributors, 2021](#)) rather than introducing a standalone  
50 framework. This decision reflects a different engineering goal: evaluating how standardized  
51 threshold Schnorr signatures can be integrated directly into a widely deployed, high-assurance  
52 elliptic-curve library. By prioritizing minimal dependencies, C89 portability, and reuse of audited  
53 primitives, the project provides a distinct systems-oriented contribution that complements  
54 existing multi-language FROST implementations.

## 55 Software Design

56 The implementation is developed as an extension module within the libsecp256k1 codebase  
57 ([Wuille & contributors, 2021](#)). Rather than re-implementing elliptic-curve primitives,  
58 secp256k1-frost builds upon the existing, well-reviewed group and scalar operations provided  
59 by the library. The project implements the protocol logic required by RFC-9591, including  
60 commitment handling, signing share computation, and signature aggregation.

61 The repository follows a structure consistent with the secp256k1 ecosystem, facilitating  
62 integration into existing projects and enabling familiar build workflows. The codebase is  
63 written in portable C89 to maximize platform compatibility. Testing and validation are  
64 performed through RFC test vectors, unit tests, and continuous integration workflows to ensure  
65 interoperability and correctness.

## 66 Design Goals and Engineering Decisions

67 The development of secp256k1-frost emphasizes engineering decisions aligned with high-  
68 assurance cryptographic software:

- 69 **Minimal dependency footprint:** no external cryptographic libraries beyond libsecp256k1.
- 70 **Portability:** adherence to the C89 standard supports diverse platforms and toolchains.
- 71 **Auditability:** reuse of existing cryptographic primitives reduces complexity and leverages  
prior security reviews.
- 72 **Interoperability:** seamless integration with secp256k1-based infrastructures, including  
blockchain and distributed systems applications.
- 73 **Deterministic builds:** suitable for environments requiring reproducibility and controlled  
deployment pipelines.

77 These design goals differentiate the library from higher-level implementations by prioritizing  
78 integration into established low-level cryptographic ecosystems.

## 79 Use Cases

80 secp256k1-frost enables experimentation and development of threshold Schnorr signing  
81 workflows in contexts where a small binary footprint and minimal external dependencies are  
82 required. Example scenarios include:

- 83     ▪ blockchain clients and wallet infrastructures,  
84     ▪ hardware-backed or embedded signing environments,  
85     ▪ research prototypes exploring threshold cryptographic protocols,  
86     ▪ performance-sensitive distributed systems.

## 87     **Security Considerations**

88     FROST requires careful handling of nonce generation, participant coordination, and commitment  
89     verification. The implementation follows the security guidance provided in RFC 9591 and  
90     documents assumptions and safe usage patterns in the project documentation.

91     The library is designed primarily for experimentation and research use while adhering to secure  
92     engineering practices consistent with libsecp256k1.

## 93     **Research Impact Statement**

94     The project contributes to ongoing research and engineering efforts around standardized  
95     threshold cryptography by providing a reproducible and inspectable implementation aligned  
96     with RFC-9591. Its integration within the secp256k1 ecosystem enables researchers to evaluate  
97     threshold signing workflows in environments representative of real-world deployments.

98     The repository includes examples, build tooling, and testing infrastructure that support  
99     reproducibility and experimentation. The software is intended to serve as a reference point for  
100    future studies on threshold signatures, distributed signing protocols, and performance-oriented  
101    cryptographic engineering.

## 102    **AI usage disclosure**

103    Generative AI tools were used exclusively to assist in drafting and refining portions of the  
104    manuscript text. All AI-assisted text was carefully reviewed, edited, and validated by the  
105    authors to ensure accuracy, clarity, and consistency with the software and its research objectives.  
106    The software implementation, design decisions, testing infrastructure, documentation, and all  
107    technical artifacts were developed solely by the authors.

## 108    **Availability**
