⁵ Summary

⁶ LLMR is an R package that provides researchers with a single provider-agnostic interface for
⁷ generation and embeddings independently and also in inside tidy data workflows. The design
⁸ enables cross model studies, parameter sweeps, and structured extraction within familiar R
⁹ idioms. LLMR supports Ollama, OpenAI, Anthropic, Gemini, Groq, DeepSeek, xAI, Together
¹⁰ AI, and Voyage AI, and extending the support to new providers is straightforward through
¹¹ writing an S3 call method. LLMR integrates with tidyverse, runs jobs in parallel, caches
¹² repeated calls, and offers structured output via JSON Schema. The package is available on
¹³ CRAN. The source code and the development version are hosted on GitHub.

¹⁴ Statement of need

¹⁵ Researchers now employ large language models to embed text, label text, extract fields, conduct
¹⁶ vignette scale experiments, and compare models across prompts and parameters. In R, many
¹⁷ available tools bind to a single provider or require people to rewrite code when changing
¹⁸ models, which slows comparisons and makes replication difficult ([Irudaya Raj, 2023](#)). Local
¹⁹ deployments via Ollama are common in privacy sensitive work and teaching, yet local and
²⁰ hosted workflows have previously been referred to separate packages ([Gruber & Weber, 2024](#);
²¹ [Lin & Safi, 2025](#)). LLMR addresses these barriers by treating model calls as data inside tidy
²² pipelines ([Wickham et al., 2019](#)). Users define configurations for providers, run model calls as
²³ vectorized or row-wise operations, and analyze the resulting columns. This approach would
²⁴ make systematic comparisons and factorial experiments straightforward to set up, and thus
²⁵ researchers retain full control of prompts and parameters while keeping the same idiom for
²⁶ analysis. Similarly, performing combinations of text embedding and text generation is smooth
²⁷ within LLMR.

²⁸ Features

²⁹ LLMR provides a consistent configuration object for models and providers, a standard response
³⁰ with finish reasons and token counts, and a tidy pipeline that makes calls over vectors or data
³¹ frames. It supports structured output using provider switches for JSON Schema, with local
³² parsing and optional validation. Parallel execution uses the future package to scale out jobs,
³³ caching can reduce repeated cost during iterative analysis, and error handling applies retries
³⁴ with backoff and records basic diagnostics ([Bengtsson, 2021](#); [Wickham et al., 2021](#)). For
³⁵ structured output, OpenAI compatible endpoints accept response_format with json_schema
³⁶ ([OpenAI, 2024](#)), Anthropic uses tool definitions with an input_schema ([Anthropic, 2025](#)), and
³⁷ Gemini supports response_mime_type and response_schema for JSON output ([Google AI for](#)
³⁸ [Developers, 2025](#)). In fact the configuration, execution, and parsing steps are kept separate,
³⁹ and thus each portion of the workflow can be replaced or extended without modifying the rest.

40 Design Logic

41 All workflows need one or more model configurations via `llm_config`, after that, the model
42 can be called via `call_llm` for either embedding or generative calls. `llm_config` tries to
43 resolve the API key from environment variables through a sensible lookup table based on
44 provider ('OPENAI_API_KEY', 'GEMINI_API_KEY', and so on), but can also be directly
45 provided, either as the actual key string (which should be discouraged) or as the name of an
46 environmental variable.

47 Provider implementations are S3 methods of `call_llm` but given that most providers
48 follow Open AI's specifications, unsupported providers can typically be called using
49 `provider='openai'` but with an overwriting of the `api_url` argument. The rest of
50 the package is essentially wrappers around the `call_llm` function. The first layer is a
51 `call_llm_robust`.

- 52 ▪ A stateful chat object can be created by `chat_session` which provides an object with
53 methods like `$send` and `$print`.
- 54 ▪ A typical experimental workflow builds an experiment data frame where each row becomes
55 an API call (this can be done via the helper function `build_factorial_experiments`)
56 and then call `call_llm_par` (or `call_llm_par_structured` for structured calls).
- 57 ▪ A tidy implementation can use the `llm_mutate` (or `llm_mutate_structured` for struc-
58 tured calls).
- 59 ▪ Finally, a typical embedding call can be done via `get_batched_embeddings`.

60 Using the future package ([Bengtsson, 2021](#)) all functions that needs to make more than one
61 api call can be parallelized and given the low local computational cost, except for locally run
62 models, there is a considerable speed boost unless a rate-limit is hit from the provider side.

63 Structured output follows is implemented differently by different providers, and is presently
64 better supported for Open AI and Anthropic models Anthropic ([2025](#)). Gemini accepts
65 `response_mime_type` for JSON and can take `response_schema` to constrain the shape ([Google](#)
66 [AI for Developers, 2025](#)). The package also parses and validates JSON locally to keep behavior
67 consistent across providers. Parallel execution uses , and caching during development uses
68 `memoise` ([Wickham et al., 2021](#)). Error handling applies retries with exponential backoff and
69 records concise diagnostics.

70 Related work

71 In R, single-provider packages such as `openai` give direct access to one API ([Irudaya Raj, 2023](#)).
72 Several packages target local models through `Ollama` ([Gruber & Weber, 2024](#); [Lin & Safi,](#)
73 [2025](#)). Others provide a tidy interface for chats across vendors ([Brüll, 2024](#); [Rapp, 2024](#)).
74 The `Ellmer` package provides (younger than LLMR) provides cross-platform support and now
75 supports parallelization and structured outputs, but lacks support for embeddings, and its design
76 objective is not scientific experimentation.

77 These tools serve important use cases. LLMR's distinct focus is a unified research workflow
78 inside R that treats model calls as data, supports parallel factorial designs and parameter
79 sweeps, and offers provider-aware structured output with local validation. Libraries in other
80 languages, such as `LangChain`, give multi-provider abstractions in Python and JavaScript, but
81 they do not integrate with R's data analysis idiom ([Chase, 2024](#)).

82 Quality control

83 The package includes some unit tests for message normalization, structured parsing and
84 validation, and parallel utilities. Continuous integration runs on Linux, macOS, and Windows.
85 Examples that call external APIs are guarded by environment variables to avoid unintended
86 network use during checks. LLMR is available on CRAN and passes routine CRAN checks for
87 the current release.

88 **Conclusion**

89 LLMR simplifies research with and research about large language models. It makes cross-provider
90 model studies simple inside R by turning model calls into data that can be analyze with standard
91 tools. The package covers hosted and local models, supports structured output, and offers
92 parallel execution with caching and retries, which helps researchers run careful comparisons at
93 scale.
