Summary

ADRIAIndicators.jl is a Julia package for analyzing outputs from coral reef ecological models. Its primary purpose is to provide a standardized and dependency-free toolkit for transforming high-dimensional model outputs such as coral abundance by reef, time, species, and size class into lower-dimensional, interpretable metrics. The package offers a wide range of functions, from simple aggregations and unit conversions to more complex indices and estimators derived from regression models. These tools help with the estimation of functional diversity, juvenile abundance, shelter volume, fish biomass, and overall reef condition, enabling consistent and comparable analysis across different coral ecology models such as CoralBlox (Ribeiro de Almeida et al., 2025, 2026), C~Scape (Cresswell et al., 2024), ReefMod (Bozec et al., 2022), and CoCoNet (Condie, 2022).

Statement of Need

Models of coral reef ecosystems often produce large volumes of high-dimensional data. There is a need for standardized tools to summarize and analyze these model outputs to facilitate inter-model comparison of environmental projections and communicate results to managers and stakeholders. ADRIAIndicators.jl provides a set of standard indicator metrics that can be used to summarize reef state in ecological model outputs. These were originally implemented within the ADRIA.jl Decision Support package (Iwanaga et al., 2025) but were being reproduced in many workflows that did not use ADRIA.jl. Separating these indicators from ADRIA.jl is part of efforts to better compartmentalize code in a more reusable and interoperable manner.

ADRIAIndicators.jl is written in Julia (Bezanson et al., 2017), a high-level, high-performance programming language for technical computing. This package is designed to be easy to use, and provides an in-place option for all metrics for any eventual wrappers that may be implemented in other languages such as Python and R. Such wrappers could be developed leveraging Julia's support for language interoperability and compilation capabilities (such as those provided by JuliaC.jl).

State of the Field

In the field of coral reef ecology, models such as ReefMod (Bozec et al., 2022), C~Scape (Cresswell et al., 2024), and CoCoNet (Condie, 2022) have historically employed internal,

40 custom-coded implementations for calculating ecological indicators. This lack of modularity
 41 often leads to duplicate development efforts for common metrics (e.g., Simpson's Diversity or
 42 unit conversions) and can introduce subtle inconsistencies in the calculation of more complex
 43 indicators like Shelter Volume (Urbina-Barreto et al., 2021) or the Reef Condition Index
 44 (Heneghan et al., 2026).

45 ADRIAIndicators.jl addresses these challenges by providing a standalone, model-agnostic library
 46 that decouples ecological indicators from specific ecological models. This approach allows
 47 researchers to apply identical analytical pipelines to outputs from diverse modeling platforms,
 48 facilitating rigorous cross-model benchmarking and ensuring that management decisions are
 49 based on comparable ecological signals.

50 Software Design

51 ADRIAIndicators.jl is designed for high performance and minimal overhead, leveraging Julia's
 52 (Bezanson et al., 2017) strengths in numerical computing. The package uses multiple dispatch
 53 to handle different output dimensions (e.g., 4D arrays for single scenarios vs. 5D arrays for
 54 ensemble outputs) while maintaining a consistent API. Key design features include:

- 55 ▪ **In-place Operations:** All metrics provide mutating versions (indicated by appending ! to
 56 the function name) to allow for memory-efficient processing of large-scale reef simulation
 57 data without unnecessary allocations.
- 58 ▪ **Dependency-Free:** The core library has zero external package dependencies, ensuring
 59 long-term stability and ease of integration into other modeling suites.
- 60 ▪ **Dimensional Consistency:** Functions strictly adhere to the [Time, Groups, Sizes,
 61 Locations, Scenarios] dimensional order, simplifying data preparation for end-users.

62 Available Indicators

63 The indicators implemented in ADRIAIndicators.jl are classified into three categories:
 64 Aggregations, Conversions, and Metrics. Aggregations are convenience methods for reducing
 65 the dimensionality of data by summarizing arrays. Conversions handle transformations between
 66 different units or representations of coral cover. Metrics derive higher-level, interpretable
 67 indicators from the raw model data, such as coral diversity, shelter volume, and composite
 68 indices for reef health.

Metric Name	Type	Reference
Relative Cover	Aggregation	
Relative Location Taxonomy Cover	Aggregation	
Relative Taxonomy Cover	Aggregation	
LTMP Cover	Aggregation	
LTMP Location Taxonomy Cover	Aggregation	
LTMP Taxonomy Cover	Aggregation	
Relative Juveniles	Aggregation	
Relative Location Taxonomy Juveniles	Aggregation	
Relative Taxonomy Juveniles	Aggregation	
Relative Habitable Cover to Reef Cover	Conversion	
Reef Cover to Relative Habitable Cover	Conversion	
Absolute Shelter Volume	Metric	(Aston et al., 2022; Urbina-Barreto et al., 2021)
Relative Shelter Volume	Metric	-
Coral Diversity	Metric	(Hill, 1973)
Coral Evenness	Metric	-

Metric Name	Type	Reference
Reef Condition Index	Metric	(Heneghan et al., 2026)
Reef Fish Index	Metric	(Graham & Nash, 2013)

69 A dash (-) in the 'Reference' column indicates the reference is the same as the entry directly
70 above it.

71 Usage

72 The order of dimensions is always the same in ADRIAIndicators.jl,

- 73 1. Time
- 74 2. Groups
- 75 3. Sizes
- 76 4. Locations
- 77 5. Scenarios

78 If a dimension is missing then the order remains the same however the missing dimensions are
79 excluded. Furthermore, all metrics have an option to provide a buffer as input in the cases
80 where one wants to write the metric into an existing array or sub-array. This implementation
81 is relied upon by functions that allocate the returned array as-well and was chosen to account
82 for any decisions in the future where another language may wrap this library and need to pass
83 memory that is not managed by Julia.

using ADRIAIndicators

Create some dummy model output data

n_timesteps = 75

n_groups = 5

n_sizes = 7

n_locations = 3806

Raw model coral cover outputs with dimensions [timesteps · groups · sizes · locations]

raw_model_cover = rand(Float64, n_timesteps, n_groups, n_sizes, n_locations);

Juveniles mask with dimensions [sizes]

is_juvenile = [true, true, false, false, false, false, false];

Calculate and allocate new array for metric

rel_juveniles = relative_juveniles(raw_model_cover, is_juvenile);

Users can provide output buffers if it is more convenient for them

rel_juveniles_out = zeros(Float64, n_timesteps, n_locations);

relative_juveniles!(raw_model_cover, is_juvenile, rel_juveniles_out);

84 Research Impact

85 ADRIAIndicators.jl provides a standardized collection of metrics for the analysis of reef
86 model outputs, supporting consistent comparative studies and ensemble modeling efforts.
87 By establishing a shared library of indicators, the package ensures that different simulation
88 platforms can summarize raw outputs using identical mathematical formulations, facilitating
89 like-for-like comparison across workflows.

90 Currently, the package provides the mathematical definitions and computations for the metrics
 91 module of ADRIA.jl (Iwanaga et al., 2025), a decision-support platform used to evaluate
 92 coral reef intervention decisions. In this workflow, ADRIAIndicators.jl summarizes the high-
 93 dimensional spatial-demographic projections from CoralBlox (Ribeiro de Almeida et al., 2025)
 94 into standardized indicators, such as relative shelter volume and reef condition indices, which
 95 are then fed directly into ADRIA's decision-support algorithms. Similarly, CScapeInterface.jl
 96 (Haller-Bull, 2026) leverages the package to post-process and export C~Scape (Cresswell et
 97 al., 2024) simulation results, allowing these high-fidelity spatial projections to also be fed into
 98 ADRIA's analysis platform for the same analysis as CoralBlox.jl. Furthermore, usage is planned
 99 for the ReefGuide tool (White et al., 2026), a web-based assessment platform.

100 Decoupling these indicators from ecological models ensures that different coral ecology
 101 models such as CoralBlox, C~Scape, or observational data are summarized consistently. This
 102 standardized definition of metrics is essential for large-scale collaborative initiatives like the
 103 Reef Restoration and Adaptation Program (RRAP), while the package's zero-allocation design
 104 ensures that post-processing massive simulation ensembles does not become a computational
 105 bottleneck. Additionally, the package facilitates the sharing of metrics with other reef systems
 106 beyond the Great Barrier Reef, where they are currently used.

107 AI Usage Disclosure

108 Gemini 2.5 Pro and Gemini 3 Pro were used in the development of tests for all implemented
 109 metrics in ADRIAIndicators.jl and were reviewed by the authors to ensure correctness.

110 Acknowledgements

111 AIMS acknowledges the Traditional Owners of the Land and Sea Country on which these
 112 indicators were developed. This package originally existed as a module of the ADRIA.jl platform
 113 and is maintained by the Australian Institute of Marine Science (AIMS) Decision Support team.
 114 Work was conducted and funded as part of the Reef Restoration and Adaptation Program
 115 (RRAP) and includes additional work funded by the Great Barrier Reef Foundation (GBRF).
