Summary

The policyengine Python package ([PolicyEngine Contributors, 2026](#)) is open-source software for analyzing how tax and benefit policies affect household incomes and government budgets in the US and UK. It gives analysts a common workflow for running simulations on representative microdata or custom households and for comparing current law with proposed reforms. Country-specific rules live in dedicated packages (policyengine-us and policyengine-uk), while policyengine provides shared tools for datasets, reforms, outputs, and reproducible release bundles. The package also powers the interactive web application at policyengine.org.

Statement of Need

Tax-benefit microsimulation models are standard tools for evaluating the distributional impacts of fiscal policy. Governments, think tanks, and researchers use them to estimate how policy reforms affect household incomes, poverty rates, and government budgets. In practice, however, analysts work across separate components: statutory rules, representative microdata, reform definitions, and distributional outputs live in different tools and interfaces. Reproducing a baseline-versus-reform workflow, or carrying the same analysis pattern from one country model to another, therefore often requires bespoke scripts and project-specific conventions. Historical replication is especially difficult when policy rules, analysis tooling, and representative microdata are versioned independently and the analyst must reconstruct which combination produced a published estimate.

The policyengine package provides a consistent Python API for tax-benefit analysis across multiple country models. Users can supply their own microdata or use companion representative datasets, then compute the impact of current law or hypothetical reforms, including parametric changes to existing policy parameters and structural modifications to the tax-benefit system, on any household or a national population. The country-specific calculate_household functions (pe.us.calculate_household and pe.uk.calculate_household) compute results for a single household, while the Simulation class runs population-level analysis on representative survey datasets with calibrated weights. Reforms take the same flat {"param.path": value} shape in both entry points. Optional behavioral-response assumptions, such as labor supply elasticities, are applied after the static reform. Version-pinned releases reduce the bookkeeping needed for replication.

State of the Field

Microsimulation, which Orcutt (1957) pioneered and Bourguignon and Spadaro (2006) surveyed for redistribution analysis, underpins much of modern fiscal policy evaluation. In the US,

39 TAXSIM (Feenberg & Coutts, 1993) at the National Bureau of Economic Research provides
40 tax calculations, while the Congressional Budget Office and Tax Policy Center maintain
41 microsimulation tax models (Congressional Budget Office, 2018; Tax Policy Center, 2022). In
42 the UK, the primary microsimulation models are UKMOD, which the Institute for Social and
43 Economic Research (ISER) at the University of Essex maintains as part of the EUROMOD
44 family (EUROMOD, 2026; Sutherland & Figari, 2013); HM Treasury's Intra-Governmental
45 Tax and Benefit Microsimulation model (IGOTM) (HM Treasury, 2025); and TAXBEN, which
46 the Institute for Fiscal Studies maintains (Waters, 2017).

47 OpenFisca (OpenFisca Contributors, 2024) initiated the open-source approach to tax-benefit
48 microsimulation in France. Other open-source efforts include the Policy Simulation Library, a
49 collection of policy models and data-preparation routines (Policy Simulation Library, 2026), and
50 The Budget Lab's public US tax-model codebases, including Tax-Simulator and Cost-Recovery-
51 Simulator (The Budget Lab at Yale, 2024, 2025). The PolicyEngine developers originally forked
52 the codebase from OpenFisca and built it on the policyengine-core framework (Woodruff et
53 al., 2024).

54 Existing tools serve complementary needs — country-specific microsimulation (TAXSIM,
55 TAXBEN, IGOTM) or simulation infrastructure without a shared cross-country analyst API
56 (policyengine-core, OpenFisca) — leaving a gap in the open-source ecosystem. The
57 policyengine package fills this gap by adding shared dataset management, a stable baseline-
58 versus-reform pattern, structured output types for distributional and regional analysis, and
59 interfaces for downstream dashboards and reports. Concretely, the package provides reusable
60 outputs such as Aggregate, ChangeAggregate, and IntraDecileImpact, together with bundled
61 analyses such as economic_impact_analysis(). This separation lets country-model packages
62 focus on statutory rules while shared analysis methods evolve independently.

63 Table 1: Comparison of policyengine with selected tax-benefit microsimulation tools. Entries
64 refer to capabilities documented for external users at the time of submission.

Table with 5 columns: Dimension, policyengine, TAXSIM, UKMOD, OpenFisca. Rows include Open source, Country coverage, Tax and benefit analysis, Python-native implementation, and Shared reform and output API across countries.

65 Software Design

66 The PolicyEngine software stack has four components. policyengine-core provides reusable
67 simulation abstractions, versioned parameters, and dataset interfaces that country packages
68 share (Woodruff et al., 2024). The policyengine-us and policyengine-uk packages
69 contain statutory logic, variables, and entity structures specific to each tax-benefit system.
70 The policyengine package is the analyst-facing component: it defines shared simulation
71 orchestration, structured output types, and canonical baseline-versus-reform workflows such as
72 economic_impact_analysis(). Companion data repositories hold enhanced survey microdata
73 derived from the Current Population Survey (CPS) (Woodruff & Ghenis, 2024) and Family
74 Resources Survey (Department for Work and Pensions et al., 2021). The package does not
75 include a macroeconomic model and does not capture general equilibrium effects.

76 This architecture reflects two deliberate trade-offs. Keeping country statutory rules in separate
77 packages, rather than bundling them into a monolithic tool, lets each country model release
78 independently; the cost is that policyengine must track and certify compatible combinations.
79 Modeling reforms statically, with optional post-hoc behavioral responses, gives fast and
80 deterministic baselines at the expense of general equilibrium effects, which are better suited to
81 dedicated macroeconomic models.

Figure 1: PolicyEngine runtime architecture. Inputs (rules, microdata, and behavioral responses) flow through the simulation pipeline to produce structured outputs.

82 For reproducibility, the top-level package acts as a certification boundary across these
83 components. Country data repositories build immutable microdata artifacts and publish release
84 manifests with checksums and the country-model version used during data construction.
85 Bundled country manifests in policyengine then certify the runtime bundle: the runtime
86 country-model version, the microdata-package release, the dataset artifact, and the
87 compatibility basis linking that runtime model to the build-time data provenance. Analysts can
88 request a dataset such as `enhanced_frs_2023_24`, while the runtime resolves it to a specific
89 versioned artifact and records both runtime and build-time provenance. The same certification
90 record can be emitted as a TRACE Transparent Research Object declaration (TRACE Project,
91 2024), so the internal bundle and data manifests remain the operational source of truth while
92 a standardized signed provenance document is available for external exchange.

93 At runtime, a simulation combines a country-model version, household microdata, and an
94 optional reform; country packages can also apply behavioral responses, such as labor supply
95 elasticities, after the static policy reform. The policyengine package then produces reusable
96 outputs for decile changes, program statistics, poverty, inequality, and regional impacts.
97 Because the runtime exposes the resolved certified bundle and compatibility basis, results
98 can be traced to a specific policyengine release, runtime country-model release, microdata
99 release, versioned dataset artifact, and build-time country-model version. Population-scale
100 runs operate on representative survey microdata and can require several gigabytes of memory;
101 the US enhanced CPS pipeline is the most demanding of the bundled workloads.

102 The following household-level example computes a household's net income under baseline law
103 and under a reform that doubles the US single-filer standard deduction (to \$32,200 for 2026):

```

import policyengine as pe

household = dict(
    people=[{"age": 40, "employment_income": 50_000}],
    tax_unit={"filing_status": "SINGLE"},

```

```

household={"state_code": "CA"},
year=2026,
)

baseline = pe.us.calculate_household(**household)
reformed = pe.us.calculate_household(
    **household,
    reform={"gov.irs.deductions.standard.amount.SINGLE": 32_200},
)
# reformed.household.household_net_income exceeds
# baseline.household.household_net_income for this household.

```

Parametric reforms take the same flat dict shape at the population level: the Simulation class accepts `policy={"gov.irs.deductions.standard.amount.SINGLE": 32_200}` alongside a dataset and a pinned country-model version. This paper describes policyengine version 4.10.0 (PolicyEngine Contributors, 2026), and the checked-in UK reproduction script `examples/paper_repro_uk.py` documents an executable population-level workflow using a pinned interpreter (`uv run --python 3.14 --extra uk python examples/paper_repro_uk.py`).

Research Impact Statement

PolicyEngine has seen use in government, policy, and research settings. In the UK, HM Treasury registered PolicyEngine in the Algorithmic Transparency Recording Standard as a tool under evaluation by its Personal Tax, Welfare and Pensions team (HM Treasury, 2024), and co-author Nikhil Woodruff adapted PolicyEngine during an Innovation Fellowship with the data science team at 10 Downing Street (Woodruff, 2026). In the US, the Joint Economic Committee built an immigration fiscal impact calculator on top of PolicyEngine's microsimulation model (Joint Economic Committee, U.S. Congress, 2026).

The package has also been used in external policy analysis and validation exercises. Under a memorandum of understanding with the Federal Reserve Bank of Atlanta, PolicyEngine runs three-way comparisons against TAXSIM and the Atlanta Fed's Policy Rules Database (Federal Reserve Bank of Atlanta, 2021). Organizations including the Niskanen Center and the National Institute of Economic and Social Research have used PolicyEngine in published distributional analyses (McCabe & Sargeant, 2024; Mosley et al., 2025), and co-author Max Ghenis and Jason DeBacker presented related methodology work on the Enhanced CPS at the 117th Annual Conference on Taxation of the National Tax Association (Ghenis & DeBacker, 2024). Additional examples of public-facing use include research collaborations and published analyses with the Better Government Lab, the Beeck Center at Georgetown University, the Institute of Economic Affairs, and Matt Unrath at the University of Southern California (Ghenis, 2024b; Institute for Research on Poverty, 2025; Kennan et al., 2023, 2025; Woodruff, 2024, 2025).

Acknowledgements

Arnold Ventures (Arnold Ventures, 2023), NEO Philanthropy (Ghenis, 2024a), the Gerald Huff Fund for Humanity, and the National Science Foundation (NSF POSE Phase I, Award 2518372) (National Science Foundation, 2025) funded this work in the US. The Nuffield Foundation has funded the UK work since September 2024 (Nuffield Foundation, 2024). These funders had no involvement in the design, development, or content of this software or paper. All authors are employed by PolicyEngine and may benefit reputationally from the software's adoption; this relationship is disclosed here as a potential conflict of interest.

We thank all PolicyEngine contributors and the OpenFisca community for the microsimulation framework from which PolicyEngine was forked (OpenFisca Contributors, 2024). We

141 acknowledge the US Census Bureau for providing access to the Current Population Survey,
142 and the UK Data Service and the Department for Work and Pensions for providing access to
143 the Family Resources Survey.

144 AI Usage Disclosure

145 The authors used generative AI tools, specifically Claude Opus 4 by Anthropic (Anthropic, 2026),
146 to assist with code refactoring. Human authors reviewed, edited, and validated all AI-assisted
147 outputs and made all design decisions regarding software architecture, policy modeling, and
148 parameter implementation. The authors remain fully responsible for the accuracy, originality,
149 and correctness of all submitted materials.
